

## 8. Example of flows: (de) Laval Nozzle

- Consider steady flow in a tube of variable cross-section,  $A(z)$ .

- Mass conservation (4.1)  $\rightarrow$

$$\underline{\nabla} \cdot (\rho \underline{u}) = 0$$

- or

$$\int_V \underline{\nabla} \cdot (\rho \underline{u}) dV = \int_s \rho \underline{u} \cdot d\underline{S}$$

- But there is no flow through the sides of the tube, so this is just

$$\rho u A = \text{constant} = \dot{M} \quad (8.1)$$

Mass  
loss rate

- Steady momentum equation (no gravity)

$$(\underline{u} \cdot \underline{\nabla}) \underline{u} = -\frac{1}{\rho} \underline{\nabla} p = -\frac{1}{\rho} \underline{\nabla} \rho \frac{dp}{d\rho} \quad (8.2)$$

- But from (8.1)

$$\ln \rho + \ln u + \ln A = \ln \dot{M}$$

$$\therefore \frac{\underline{\nabla} \rho}{\rho} = \underline{\nabla}(\ln \rho) = -\underline{\nabla}(\ln u) - \underline{\nabla}(\ln A)$$

- And so (8.2) becomes

$$(\underline{u} \cdot \underline{\nabla}) \underline{u} = [\nabla(\ln u) + \nabla(\ln A)] \frac{dp}{d\rho}$$

$\nearrow$   $(\underline{u} \cdot \underline{u}) \nabla \ln u$  (Assume irrotational)  $\nwarrow$   $c_s^2$  (see later)

i.e.

$$(u^2 - c_s^2) \nabla(\ln u) = c_s^2 \nabla(\ln A)$$

- Or

$$(u^2 - c_s^2) \frac{\nabla u}{u} = c_s^2 \frac{\nabla A}{A} \quad (8.3)$$

- So.. a min or max in A:

- Corresponds to either
  - a min or max in  $\underline{u}$  or
  - $u=c_s$

- Conversely, gas can *only* make a sonic transition (from sub- to supersonic or vice versa) at a max or min of the nozzle.

- In subsonic regime,  $(u^2 - c^2) < 0$

– if A gets smaller,  $\underline{u}$  gets larger

- In supersonic regime,  $(u^2 - c^2) > 0$

– if A gets larger,  $\underline{u}$  gets larger

- So a nozzle can be used to accelerate flow from subsonic -> supersonic

$\underline{u}$  increases monotonically

- Note also from (8.2)

$$u^2 \underline{\nabla} \ln u = -c_s^2 \underline{\nabla} \ln \rho$$

Subsonic:     $u \ll c_s$      $\underline{\nabla} \ln u \gg \underline{\nabla} \ln \rho$

Nearly incompressible (so often a good assumption for everyday flows); acceleration important

Supersonic:     $u \gg c_s$      $\underline{\nabla} \ln u \ll \underline{\nabla} \ln \rho$

Nearly constant  $u$ ; pressure gradients not important in acceleration

## Getting the velocity:

- Apply Bernoulli (7.3):

$$\frac{1}{2}u^2 + \int \frac{dp}{\rho} = \text{const}$$

- Assume isothermal

$$\frac{1}{2}u^2 + c_s^2 \ln \rho = \text{const}$$

- At a max/min of the nozzle,  $A=A_m$  and  $u=c_s$
- So, if  $M$ ,  $c_s$  and  $A(z)$  are specified, (8.1) gives

$$\rho_{Am} = \frac{\dot{M}}{u_{Am} A_m} = \frac{\dot{M}}{c_s A_m}$$

- Wave Bernoulli at it...

$$\frac{1}{2}u^2 + c_s^2 \ln \rho = \frac{1}{2}c_s^2 + c_s^2 \ln \rho_{Am}$$

$$u^2 = c_s^2 [1 + 2 \ln(\rho_{Am} / \rho)]$$

- But, from (8.1)

$$\frac{\rho_{Am}}{\rho} = \frac{uA}{c_s A_m} \quad (8.4)$$

- And so

$$u^2 = c_s^2 [1 + 2 \ln(uA/c_s A_m)] \quad (8.5)$$

- Hence if we know  $A(z)$ , get  $u(z)$  from (8.5) and use (8.1) to get  $\rho(z)$ .
